What GAO Found

Disparities in income and wealth among older households have become greater over the past 3 decades, according to GAO’s analysis of Survey of Consumer Finances (SCF) data. GAO divided older households into five groups (quintiles) based on their income and wealth. Each year of data in the analysis, and, thus, each quintile, included different sets of households over time. Average income and wealth was generally higher over time (see fig. 1 for average income), disproportionately so for the top quintile (top 20 percent). For example, in 2016, households in the top quintile had estimated average income of $398,000, compared to about $53,000 for the middle quintile and about $14,000 for the bottom quintile. GAO also found that for quintiles with lower wealth, future income from Social Security and defined benefit pensions provide a relatively significant portion of resources in retirement for those who expect such income.

Figure 1: Estimated Average Household Income of Older Households by Income Quintiles, 1989 to 2016

Average household income (in 2016 dollars)

50,000  100,000  150,000  200,000  250,000  300,000  350,000  400,000  450,000

Source: GAO analysis of 1989 through 2016 Survey of Consumer Finances data.

Notes: Income is aggregated across all sources, such as wages, Social Security benefits, or withdrawals from retirement savings accounts. Averages represent mean estimates. The shaded portions of the figure represent 95 percent confidence intervals; the intervals for some quintiles are less visible because they are very narrow. The Survey of Consumer Finances is conducted every 3 years.

years. Older households are those where the survey respondents or any spouses or partners were aged 55 or older in the year of the survey. GAO ranked these households by their income and broke them into five equally sized groups, or quintiles. Each year of data in our analysis, and, therefore, each quintile included different sets of households over time.

A substantial number of older Americans born from 1931 through 1941 lived at least into their 70s or early 80s, according to GAO’s analysis of data from the Health and Retirement Study (HRS), a nationally representative survey which follows the same individuals over time. GAO divided individuals born from 1931 through 1941 into quintiles based on their mid-career household earnings using records from the Social Security Administration. GAO’s analysis, as well as that of other researchers, shows that differences in income, wealth, and demographic characteristics were associated with disparities in longevity. However, even with these disparities, we found a substantial number of people in the sample were alive in 2014, including those with characteristics associated with reduced average longevity, such as low earnings (see fig. 2) and low educational attainment. Taken all together, individuals may live a long time, even individuals with factors associated with lower longevity, such as low income or education. Those with fewer resources in retirement who live a long time may have to rely primarily on Social Security or safety net programs.

Notes: Older Americans ages 51 to 61 in 1992 were ages 73 to 83 in 2014. GAO defined mid-career household earnings based on earnings reported to the Social Security Administration for years when the survey respondents were ages 41 through 50, as well as the earnings of their spouses or partners during those years if the respondents were part of a couple in 1992. GAO ranked these households by their mid-career household earnings and broke them into five equally sized groups, or quintiles. The proportion of individuals alive in 2014 was estimated using a Kaplan-Meier survival analysis.

GAO’s analysis of HRS data also found that disparities in household income decreased while disparities in wealth persisted as a cohort of older Americans aged from approximately their 50s into their 70s or early 80s. Income disparities decreased between higher- and lower-earning households because higher-earning households saw larger drops in income over time, indicating the possible transition from working to retirement. For example, we estimated median income for the top mid-career earnings group decreased by 53 percent while estimated median income for the bottom earnings group decreased by 36 percent over the same period. Wealth remained relatively steady for households in the bottom three earnings groups over the time period GAO examined, while households in the top two earnings groups experienced larger fluctuations in wealth. GAO estimated that median retirement account balances and median home equity increased across earnings groups for households that had these assets. However, the continued wealth disparities may be due to significant differences in the median value of retirement accounts and home equity between higher- and lower-earning households. GAO also found that white households in the bottom two earnings groups had higher estimated median incomes, and white households in all earnings groups generally had greater estimated median wealth, than racial minority households in those earnings groups. In addition, within each earnings group, households headed by someone with at least some college education generally had higher median incomes and wealth than households headed by someone who did not attend college.
